FORENSIC FAIL?

As research continues to underscore the fallibility of forensic science, the judge’s role as gatekeeper is more important than ever.
This is a time of crisis but also a time of great promise in forensic science. The terminology used to express conclusions, error-rate statistics, and the fundamental conception of what experts are doing are all in flux. Traditional disciplines like latent fingerprinting, which has been done the same way for over a hundred years, are on the cusp of a transformation. In that field, analysts would typically state without qualification that a print was a “match” and came from the defendant, and that there was a zero probability of an error. Now it is well understood that no human expertise is immune from error, any subjective comparison is inherently probabilistic, and expertise depends on the proficiency of the person doing the analysis.

Today, as Thompson and colleagues describe, forensic expert conclusions are becoming more appropriately cautious in many disciplines. The 2016 White House Presidential Council of Advisers on Science and Technology (PCAST) report emphasized the need to validate forensics, including by studying error rates and informing jurors of those error rates. The 2017 American Association for the Advancement of Science (AAAS report), which Thompson co-authored, recommended such changes as well and made more detailed recommendations concerning the language to be used in latent fingerprinting. Indeed, forensic conclusions may soon be quantitative; Thompson describes the move to incorporate statistics in forensics. Researchers are hard at work on methods to use algorithms to supplement or even supplant the subjective judgment of individual forensic analysts.

Next, Jay Koehler focuses on reliability: What are the error rates for forensics? As Koehler notes, many people assume that forensics are nearly infallible. If jurors think that forensic experts are infallible but judges know they are not,
then what is the obligation of a judge to ensure that the jury is informed about the limitations of the science?

Rule 702 states that an expert may testify if using “reliable principles and methods,” which are “reliably applied” to the facts. Or as the Advisory Committee states, judges shall “exclude unreliable expert testimony.” Koehler is right that now is the time to ask whether the “reliability rule” adopted in *Daubert* and in Rule 702 is being appropriately used by the judiciary.

Koehler also highlights the (sometimes quite aggressive) responses to the PCAST report. Some members of government agencies and professional organizations called the report unfounded and biased for suggesting that a range of forensic disciplines lack empirically validated reliability. They suggest there is no problem with continuing to rely on an expert’s experience and subjective professional judgment.

In response, Koehler emphasizes judges should not admit evidence just because an expert claims to have experience. Judges should not admit evidence just because other judges have done so for a long time. Judges should not admit evidence just because experts take (extremely unrealistic and easy) proficiency tests. Experts should have to show that their work is reliable and that they are truly proficient. That is, after all, what Rule 702 demands. The problem, Koehler concludes, is not with the text of the rule, but its laissez-faire application by judges.

Finally, Pate Skene further explores what the proper role of judges is at a time when empirical evidence to support so many forensics can be mixed or lacking. Skene describes how judges have themselves raised real questions about the reliability of commonly used forensic techniques. Skene focuses on the problem that for many forensic techniques, well-designed empirical studies have not yet been conducted to validate the reliability of the techniques. The PCAST report emphasized as much.

Turning back to jurors, Skene highlights how important it is for judges not to just exercise their role as gatekeeper, but also to ensure that when forensic evidence is admitted, jurors hear about its limitations. Jurors are highly receptive to information about error rates in forensic techniques and information about the proficiency of particular forensic analysts, as Greg Mitchell and I have shown in several studies. Skene suggests that such information may be conveyed by jury instructions or by additional experts who can explain error rates or reliability concerns to the jury. Skene also suggests that the need for judicial intervention to educate jurors will be greatest when there is less known about the reliability of a forensic technique.

Twenty-five years after *Daubert*, the reliability revolution is still nascent. In an era of plea bargaining and the vanishing criminal trial, it is all the more important that judges safeguard reliability, since it will be the rare occasion when a fact-finder can scrutinize reliability in the courtroom. It is equally important that crime labs themselves incorporate blind proficiency and error management as part of routine quality control. In response to quite complex problems, these thought-provoking contributions from Koehler, Thompson, and Skene set out a clear agenda to bring reliability back into our criminal courtrooms.
